MID-PACIFIC OCEANOGRAPHY PART IX, OPERATION NORPAC

The need for a survey to provide a synoptic picture of the oceanographic and biological conditions of the entire North Pacific as a background for fisheries investigations and for effectively describing the circulation has long been recognized. It was also recognized that such a survey would require the cooperative and coordinated efforts of several oceanographic activities and their vessels. A proposal for such a cooperative venture, that finally culminated in the quasi-synoptic survey known as NORPAC, was made at the Fifth Pacific Tuna Conference in November 1954. Those present at the Conference represented agencies of Canada and the United States interested in tuna research and related oceanography. The Scripps Institution of Oceanography, designated as the coordinating agency, was instructed to enlist the aid of Japanese agencies. After considerable planning and coordination of the field programs, the vessels from the various participating agencies completed the survey in July-September 1955. Their tracks are indicated in the frontispiece.

The Pacific Oceanic Fishery Investigations (POFI) of the U. S. Fish and Wildlife Service, Honolulu, T. H., assigned one vessel, the Hugh M. Smith (HMS) to the NORPAC oceanographic survey, and one vessel, the John R. Manning (JRM), to exploratory fishing during this period. The Hugh M. Smith surveyed the area from the Hawaiian Islands to 49°30'N., from 157°30'W. to 180°, during the period of July 15 through August 28, 1955 (fig. 1). The data collected on this cruise compose the main body of this report. The John R. Manning fished in the area northeast of the Hawaiian Islands between 152°30'W. and the west coast of the United States from 30°N. to 47°N. (Appendix, fig. 7) from July 15 through September 10, 1955. The limited oceanographic observations of the Manning, consisting of bathythermograph lowerings, surface salinities, and meteorological records, are given in tables 9 and 10 (Appendix).

NORPAC was opportunely timed in reference to the POFI albacore research program, a study financed by an allotment of funds through the Saltonstall-Kennedy Act in October 1954. This synoptic survey of the oceanographic and biological conditions of the surrounding area as well as the particular areas under study so early in the research program should prove invaluable to the progress of these studies, for the oceanographic and biological conditions of the albacore study area can now be evaluated in reference to a framework consisting of the entire North Pacific Ocean.

FIELD PROCEDURES

The Smith departed Pearl Harbor, T. H., on July 15, 1955; stopped at Midway Island from July 21-23 to take on water, fuel, and stores; made a bait survey of the lagoon and reef; completed her NORPAC observations, and returned to Pearl Harbor on August 28, 1955. The track and station[1] positions are shown in the frontispiece and figure 1.

Missions

A. Primary Missions:

1. Oceanography

a. Seventy-nine oceanographic stations were occupied (fig. 1 and table 1). At 67 of the stations 13-bottle casts were made to a depth of approximately 1,200 m. At twelve of the stations deeper casts were made to the maximum depth the wire would permit; six were double casts of 9 and 13 bottles each to approximately 2,000-2,500 m. and six were 13-bottle casts to approximately 1,400-1,500 m.

All Nansen bottles carried two protected reversing thermometers. All but the upper four bottles (those at approximately 100 meters or less) carried an unprotected reversing thermometer for use in determining the sampling depth.

1/ A station indicates a significant unit of scientific work which is separated in time and/or space from other units. Table 1 lists the observations made at each station. The following observations did not constitute a station and are tabulated separately: (1) trolling, (2) single BT casts, (3) weather observations, and (4) observations of fish, birds, and mammals.

At all stations where 13-bottle casts were used the spacing of the bottles (usually 6) above 300 m. was determined by the characteristic of the bathythermograph (BT) trace. At the 1,200-m. stations the remaining seven bottles were placed at the standard depths of 300, 400, 500, 600, 800, 1,000, and 1,200 m. At the stations where 13-bottle casts were made to depths of 1,400-1,500 meters the intervals between the seven deepest bottles were slightly increased. At two-cast stations the first cast was to 600 meters with 13 bottles, the spacing dependent upon the BT trace. The second had 9 bottles placed at approximately 800, 1,000, 1,200, 1,400, 1,600, 1,800, 2,000, 2,250, and 2,500 meters. As the depth of these casts was decreased because of the loss of wire, the intervals were decreased.

b. Salinity samples were drawn from each Nansen bottle and returned to the POFI laboratory for analysis. To preclude evaporation, each sample was stoppered with a paraffin-impregnated cork in addition to the screw cap. Additional samples were drawn at several stations at the northern end of the 180° and 165°W. transects and analyzed aboard ship to make certain that the sections extended into the Subarctic water. Additional surface salinity samples were taken at all off station BT's (last column, table 2).

c. Dissolved oxygen analyses using the Winkler method were made aboard ship on samples from each depth and from all the oceanographic stations.

d. Inorganic phosphate analyses were also made aboard ship. Subsequent analyses of the resulting data showed that the Automatic Servo-Operated Photometer was malfunctional and the data are not useable.

e. Bathythermograph lowerings were made twice at each station and at 30-mile intervals between stations. On station the first lowering was made on arrival to determine the vertical distribution of temperature which was then used as a guide in spacing the Nansen bottles. The second was made as the cast was being tripped in order to obtain a continuous record of the vertical temperature for use with the reversing thermometer values in constructing the temperature-depth curves. The bathythermograph log sheets (Log Sheet "B") are summarized in table 2, and figures 2 to 6 are plots from the corrected BT slides.

f. The thermal element of the ship's recording thermograph failed after 8 days of operation, so a continuous record of the surface temperature was obtained only on the run from Pearl Harbor to Midway Island. In the northern part of the area, north of 40°N., where sharp changes of temperature were encountered, hourly bucket temperatures were taken in addition to the BT temperatures at 30-mile intervals.

g. No GEK current measurements were taken because of instrument failure.

h. Secchi disk observations of water transparency and color measurements (Forel scale) were made at 39 stations. The results are listed in table 1.

i. Bottom profiles were obtained over about 25 percent of the track by means of the EDO echo sounder. The EDO worked only intermittently on the run to Midway, where it was adjusted by technicians from the U. S. Naval Air Station. It was then operated continuously to about station 44 where it failed completely. The resulting data have been forwarded to the U.S.N. Hydrographic Office.

2. Plankton

a. Thirty-minute oblique hauls to a depth of 140 meters, employing a 1-meter net of 30XXX grit gauze, were made at 78 of the oceanographic stations. All nets were equipped with Atlas flowmeters, which were calibrated before and after the cruise.

The cruise plan also called for three-net oblique plankton hauls with basically the same type of nets as those used in the 140 m. hauls, to sample plankton from three levels: near the surface, the region of the thermocline (40-95 m.), and below the thermocline (95-440 m.). Three-net hauls were tried without success at the five daylight stations on the run to Midway and then abandoned. After Midway, the 140 m. oblique hauls were then supplemented with shallow oblique hauls, the depths of which were adjusted so that sampling was completely above the thermocline, or to 40 m. if there was no homogeneous surface layer. Fifteen samples from the shallow hauls made on the 172°30'W. transect were frozen for later analysis of fat, glycogen, and protein content.

B. Secondary Missions:

1. Meteorological observations

a. Synoptic marine weather observations were made daily at 0000, 0600, 1200, and 1800 GCT. In addition, certain standard weather observations accompanied all BT lowerings.

Only one storm with winds and seas which were high enough to interfere with the survey work was encountered. It passed over the vessel at 0600 GCT on July 27, 1955, at approximately 35°30'N., 179°50'W. and had winds of 40-45 knots for about 3 hours, producing 10- to 12-foot seas for about 6 hours. The high wind and seas made it necessary to omit the mid-water trawl haul and delayed one hydrographic station for 4 hours.

2. Tuna abundance

a. The wheel watch maintained a careful lookout for tuna schools, bird flocks, and scattered birds and mammals. The sightings of birds and fish are summarized in table 3. Numerous whales (mostly sperm), porpoises, and a few fur seals were sighted. The observations are tabulated in table 4.

b. Surface trolling was carried out during daylight hours. Three lines were fished while the GEK electrodes were being towed (to station 40) and 5 lines thereafter. North of the 65°F. surface isotherm on the 172°30'W., 165°W., and 157°30'W. transects the trolling speed was 7.2 knots; over the rest of the area the speed was between 9 and 10 knots. The total number of line hours at reduced speed was 217 hours and at standard speed 1,827 hours. The positions at which the catches were made, except for 1 albacore, are listed in table 5.

3. Miscellaneous biological collections

a. Stomachs of 7 of the 8 albacore taken by trolling were preserved and returned to the POFI laboratory.

b. Nineteen night-light stations were made at sea and one at Midway Island (see table 1 for positions).

c. Forty oblique hauls of 1 hour's duration were made with the 10-foot Isaacs-Kidd trawl (see table 1 for positions). Relatively productive hauls were made in, and to the north of, the zone of the subsurface temperature discontinuity.

d. Morphometrics were taken, and vertebrae, scales, and ovaries were saved from 7 albacore for racial and growth studies.

e. From station 37 to 41 large masses of a giant kelp, Alaria fistulosa, were frequently sighted. Six complete thalli including the holdfast were brought aboard from the first mass, which was sighted just before station 37 (fig. 1). The largest of the thalli was about 50 feet long, and the holdfast was about 20 inches across and weighed about 25 pounds. Several of the holdfasts were cut apart and the invertebrates removed and preserved. These included sponges, flat worms, sea anemones, annelids, starfish, brittle stars, sea urchins, sea cucumbers, sipunculoids, gastropods, and amphipods. The Alaria also had several epiphytic algae, which were preserved.

From station 81 to 87 another large kelp, Macrocystis sp., was frequently sighted. No samples were taken.

f. A bait survey was made on Sand Island of the Midway atoll. On the lagoon side about 25 buckets of iao (Atherinidae), 10 buckets of aholehole (Kuhlia sandvicensis), and 2 buckets of mullet (Mugilidae) were sighted. On the ocean side 32 buckets of aholehole and 5 of mullet were sighted.

4. Miscellaneous observations

a. At every third oceanographic station a 500-ml. sample (total, 26) was taken from a depth of 200 m. for radioactivity analysis to be made by Scripps Institution of Oceanography. At 12 of these stations a 10-liter integrated sample was taken from the mixed surface layer for radioactivity analysis as requested by Dr. Yasuo Miyake, Central Meteorological Observatory, Tokyo. Special Nansen bottle casts of 11-12 bottles spaced at intervals of 3-4 meters were made to obtain these samples (table 1).

b. At 15 stations samples (total, 126) were taken at alternate depths for deuterium analysis to be made by Woods Hole Oceanographic Institution (Dr. Alfred C. Redfield) (table 1).

c. At 7 stations along 180°, 1-liter water samples were taken from the surface and 150 m., and aliquots of at least 5 ml. were taken from the shallow plankton tows for the Medical and Biological Division of the U. S.

Atomic Energy Commission (Dr. Robert J. Buettner, U.C.L.A.-A.E.C. project) (table 1).

d. At 31 of the oceanographic stations one to seven 200-ml. water samples (total, 86) were taken from the upper 125 meters for phytoplankton studies at Scripps Institution of Oceanography (Mr. Robert N. Holmes) (table 1).

RECORDS

The following records were kept and are on file at POFI, except as otherwise noted in parentheses after the item:

Original oceanographic data "Log Sheet A"
Bathythermograph log sheet "B" (duplicates at Scripps Institution of Oceanography)
Field plots of BT temperatures
Chemical data sheets
BT slides (Scripps Institution ofOceanography)
Thermograph records
Track charts
Deck log
Occurrence of tuna schools and bird flocks log
Plankton log
Flowmeter and plankton sampler calibration log
Surface trolling log
Scientist's log
U.S.W.B. Form 1210F (U.S. Weather Records Center, Asheville, N.C.)
EDO depth recorder charts (U.S.N. Hydrographic Office)
Short form tuna morphometric sheets
Thermometer arrangement forms
Night-light fishing log
Trawling log
Barograph records (U.S.W.B.)

LABORATORY METHODS AND TECHNIQUES

A. Oceanographic data

The analyses of samples drawn from the Nansen bottles for dissolved oxygen and inorganic phosphate were made aboard ship. Oxygen concentration was determined by Winkler's method. Duplicate determinations were made for each sample; precision was in the neighborhood of 0.5 percent. Phosphate phosphorus concentration was measured with the use of the Automatic Servo-Operated Photometer, as described by Wooster and Rakestraw (1951).

Concentrations of salinity in the samples returned to the POFI laboratory were determined by a new modification of Fajan's adsorption indicator method developed at this laboratory, and adapted to Knudsen's techniques for sea water. Accuracy of the method as based on standard (Copenhagen) sea water is 0.1 percent or greater; routine precision is about 0.03 percent.

The duplicate readings of the protected and unprotected reversing thermometers made aboard ship were reduced by graphical methods to true water temperature, with an accuracy of $\pm$ 0.02°C., and the thermometric depth is combined graphically with the wire length to give the accepted depth of reversal of each bottle. These methods are described by La Fond (1951).

The observed data were plotted on a graph developed by Klein[2/] on which the coordinates are depth (or salinity, oxygen, phosphate) vs. thermosteric anomaly (the anomaly of specific volume neglecting pressure terms). Isotherms appear on the graph as slanting straight lines. The observed chemical concentrations are each plotted against the temperature-depth curve.

The temperature-depth curve was drawn using the bathythermograph curve obtained on station to aid in forming the upper portion, the curve following the shape of the BT trace but passing through the points observed with reversing thermometers. The other curves (temperature-salinity, and -oxygen) were drawn making the station-to-station changes as regular as allowed by the observed points. Values obviously in error became evident during this stage of the processing and were discarded.

Temperatures at standard depths were read from the T-depth curve, and the respective values were read and tabulated from the other curves at these temperatures. Computation of geopotential anomaly (with pressure terms neglected) was done directly from the station graphs. If the average values of thermosteric anomaly over suitable small intervals of depth (pressure) times the pressure interval in db are summed upward from some reference level, the result is the geopotential anomaly over the reference depth. The depth intervals used are 100 m. in the deeper layers and 10 m. in the thermocline and surface layer; this simplifies the multiplication by the pressure interval to a mere change in decimal place, and has the advantage of following the observed data very closely in the region of the thermocline. In practice, the value of thermosteric anomaly was read from the T-S curve at the temperature of the midpoint of the desired depth interval on the T-depth curve.

B. Plankton

In the laboratory the zooplankton samples were treated as follows:

1. All organisms above 5 cm. in longest dimension plus non-food organisms (King and Hida 1954) 2 to 5 cm. in longest dimension were removed from the sample and were not included in the volumes or group counts.

2. The wet drained volume of the remainder of the sample was determined by water displacement following the method of King and Demond (1953), except that in this case the entire sample was measured. Volumes in $cc/1000m^3$ (table 6) were estimated from the flowmeter records following the method of King and Demond (1953).

3. An aliquot of the sample (usually 1/4) was placed in a 15 x 20 cm. counting chamber and distributed as evenly as possible.

All organisms within each of 10 randomly selected square centimeters were identified down to "group" (phylum to order) and counted. The estimated number of each "group" in the total sample was obtained by multiplying the above counts by $10 \times \frac{1}{15 \times 20}$ or 30 times the aliquot denominator. The estimated numbers of organisms per 1,000 cubic meters of water strained was obtained by dividing the above total sample estimates by the cubic meters of water strained expressed in thousands. The resulting values are tabulated in table 7.

* - 95 percent by volume radiolarian and diatom "fuzz"

P - present but not countable

NOTES ON TABLE 8, TABULATED OCEANOGRAPHIC DATA, HMS 30

Where more than one cast was made on a station, they are divided in the observed data by a horizontal line, and the cast number indicated by Roman numerals.

Where the corrected paired protected thermometer readings differed by more than 0.05°C., the depth and salinity are repeated, and both temperature values are carried. σ_t and δ_t calculated using each temperature value are carried.

Weather is recorded in the ww (present weather) code given in the U. S. Weather Bureau circular M, eighth edition, Manual of Marine Meteorological Observations. Cloud coverage is in tenths of sky.

Wind velocity was measured with an anemometer 30 meters above the sea surface. The direction (given to the nearest 10°) is that from which the wind was blowing, measured through 360° from north.

In the tabulated interpolated data, values within parentheses indicate extrapolation beyond the depths of observation.

The following abbreviations, when appended to values or lines in the tabulated observed data, have the indicated meanings:

Q -- The value seems questionable, but was used in construction of the station curve.

P -- The value is poor, and while carried was not used in drawing the station curve.

NG -- The value is obviously in error, and is dropped from the tabulations.

NS -- No water sample was available for this determination.

PT -- Nansen bottle pretripped, and data are unuseable.
